Name, Scope, and Binding

Name, Scope, and Binding

- A **name** is exactly what you think it is
  - Most names are identifiers
  - symbols (like '+') can also be names

Name, Scope, and Binding

- A **name** is exactly what you think it is
  – Most names are identifiers
  – symbols (like '+') can also be names
- A **binding** is an association between two things, such as a name and the thing it names.

  – Most names are identifiers

- A **binding** is an association between two things, such as a name and the thing it names.
- The **scope** of a binding is the part of the program (textually) in which the binding is active.

Binding

Binding Time:

the point at which a binding is created or, more generally, the point at which any implementation decision is made.

Binding

Binding Time:

the point at which a binding is created or, more generally, the point at which any implementation decision is made.

- language design time program structure, possible type
- language implementation time
  - I/O, arithmetic overflow, type equality (if unspecified in manual)

Other Implementation Decisions

- program writing time
  – algorithms, names

Other Implementation Decisions

- program writing time
  - algorithms, names
- compile time
  - plan for data layout

- link time
  –layout of whole program in memory
- load time

More Implementation Decisions

- run time
  - value/variable bindings, sizes of strings
  - NOTE: run time includes
    - program start-up time
    - module entry time
    - elaboration time (point at which a declaration is first "seen")
    - procedure entry time

Binding

The terms **STATIC** and **DYNAMIC** are generally used to refer to things bound before run time and at run time, respectively.
– "static is a coarse term; so is "dynamic"

Binding Times are very important in programming languages!

Binding

- In general, early binding times are associated with greater efficiency
- Later binding times are associated with greater flexibility

Binding

- In general, early binding times are associated with greater efficiency
- Later binding times are associated with greater flexibility
- Compiled languages tend to have early binding times
- Interpreted languages tend to have later binding times

Scope Rules - Control Bindings

- Fundamental to all programming languages is the ability to **name data**
  - i.e., to refer to data using symbolic identifiers rather than addresses

Scope Rules - Control Bindings

- Fundamental to all programming languages is the ability to **name data**
  - i.e., to refer to data using symbolic identifiers rather than addresses
- Not all data is named! For example, dynamic storage in C or Pascal is referenced by pointers, not names

  - i.e., to refer to data using symbolic identifiers rather than addresses
- Not all data is named! For example, dynamic storage in C or Pascal is referenced by pointers, not names

```
double *d = (double *)malloc(8);
*d = 3.14; /* No name is bound to the value 3.14 */
/* The name ``d'' is bound to the ADDRESS containing 3.14
*/
```

Lifetime and Storage Management

- The period of time from creation to destruction is called the **LIFETIME** of a binding.

Lifetime and Storage Management

- The period of time from creation to destruction is called the **LIFETIME** of a binding.
- If object outlives binding it's **garbage**.
- If binding outlives object it's a **dangling reference**.

- The textual region of the program in which the binding is active is its **scope**.

Lifetime and Storage Management

Storage Allocation mechanisms

- Static
- Stack
- Heap

Lifetime and Storage Management

Storage Allocation mechanisms

- Static
- Stack
- Heap

Static allocation for

- code
- globals
- static or own variables

Static Example

In C, variables can be global (visible to any function)

```c
int i; /* i is global */
int f(int x) {
  return i+x;  /* i is visible inside function f */
}
main() {
  int j;   /* j is visible only within main */
  i = 10;  /* i is visible inside function main */
  j = 99;
  j = f(3); /* sets j to 13 */
}
```

Static Example

When we compile this, *i* is stored in a fixed location, while *j* is allocated on the stack

(C-to-ARM assembly from http://assembly.ynh.io/)

Two Types of Scoping

Static scoping (also called "lexical scoping")

- most familiar (Java, C)
- scope of variables known at compile time

Two Types of Scoping

Static scoping (also called "lexical scoping")

- most familiar (Java, C)
- scope of variables known at compile time

Dynamic scoping

- scope depends on order of function calls at execution time
- pretty rare nowadays

Static Scope Example (Java)

```java
public static int x,y;
public static void main(String[] args) {
    x = 10; y = 20;
    test();
    { int x = 70,y=80;
        System.out.println("x = " + x + ", y = " + y);
    }
    System.out.println("x = " + x + ", y = " + y);
}
public static void test() {
    int x = 50, y = 60;
    System.out.println("x = " + x + ", y = " + y);
}
```

Scope of **x,y**

Scope of **x,y**
("hole" in the
scope of x,y)

Scope of **x,y**
("hole" in the
scope of **x,y**)

OUTPUT:
x = 50, y = 60
x = 70, y = 80
x = 10, y = 20

What Happens Here? (Java)

```java
public static int x,y;
public static void main(String[] args) {
  x = 10; y = 20;
  test1();
}
public static void test1() {
    int x = 50, y = 60;
    test2();
}
public static void test2() {
    System.out.println("x = " + x + ", y = " + y);
}
```

Does this print "x = 10, y = 20"
or
"x = 50, y = 60" ?

What Happens in Dynamic Scoping?

```
int x,y;
start() {
    x = 10; y = 20;
    test1();        Outputs "x = 50, y = 60"
    test2();        Outputs "x = 10, y = 20"
}
test1() {
    int x = 50, y = 60;
    test2();
}
test2() {
    System.out.println("x = " + x + ", y = " + y);
}
```
